Frequency of Hypertension after 10 Years of Military Services in Bangladesh Army

H. M. Khaleduzzaman and Nafisa Jabin Mishu

ABSTRACT

Bangladesh army performs different activities in war and peace in all terrain so physical fitness is the prime requirement for military services. Though military personnel perform regular physical activities they are not immune from hypertension. Hypertension is a multivariate disease ranging from physical and psychological factors. In this study hypertension found among 16% of participants where some modifiable factors were found associated with development of early onset hypertension like lack of physical activities, increase mental stress, overweight, smoking, pattern of dietary habit, lack of awareness and abnormalities in lipid profile. Further study is required to establish these modifiable risk factors and their intervention to prevent early onset hypertension among military service personnel in Bangladesh. Which not only improve the health condition of military personnel but also increase the efficiency of Bangladesh Army as well as it will reduce the health expenditure related to hypertension.

Keywords: Military service, Hypertension, frequency, modifiable risk factors, mental stress.

I. INTRODUCTION

Military service is a service by an individual or group in an army. Army has diverse of activities during peace and war. Bangladesh Army consists of young healthy Bangladeshi soldiers. They came from different socio-economic status. They vary in their social, cultural, and educational background as well as the existing rank structure. Military persons perform difficult activities including constructions in the country and control the terrorism both hill and land area. They also perform operational activities in war situation under United Nations (UN) in mission. To perform complex task effectively physical fitness is the prime requirement for military service. Hypertension is a common phenomenon among general population, but it is not usual among military persons. No hypertensive individual is allowed to join in services though it is observed that hypertension is found in early age among military persons. Hypertensions not only increase the risk of early onset ischemic heart disease and stroke but also reduce the efficacy of military personnel. Moreover, some of the military personnel had to go to premature retirement from the services due to hypertension and its complications which ultimately influences on society.

Hypertension is a common condition. Hypertension in developing world is high which may be due to less availability and affordability of necessary antihypertensive drugs as required as that in developed countries. [1] Central obesity is strong risk factors of high prevalence of hypertension among Indian immigrants to Britain. [2] But little is known about its frequency in the Bangladesh Army.

Early hypertension among the combatants not only reduces the efficiency but also largely increases the health expenditure and health burden. This study will open an area of further research and appropriate action regarding early detection and prevention of long-term complications among military service personnel.

II. MATERIALS AND METHODS

This was a cross-sectional study which was carried out over a sample of 245 military personnel after 10 years of services but below 40 years of age in Bangladesh Army. The study was done at Combined Military Hospital-Dhaka during six month period, beginning July 2019 to December 2019, without interruption. Blood pressure was measured with an aneroid sphygmomanometer. Two measurements of the blood pressure were taken on the right arm in sitting position relaxed for 5 minutes and at least 30 minutes after they had last smoked, exercised, or ingested caffeine. The mean of the measures was used. The cut-off points for hypertension were ≥ 140 mmHg for systolic pressure and ≥ 90 mmHg for diastolic pressure or who had reported taking medicine for high blood pressure. The study variables were included risk factors for hypertension. Data were collected by purposive Simple random sampling method with a structured questionnaire. Finally, data analysis was done using SPSS-25.

Military persons who served 10 years in Bangladesh Army and those who have given informed consent were included in this study. One the other hand who was suffering from
chronic kidney disease, thyroid disorder, Phaeochromocytoma, renal artery stenosis was excluded from this study. Participants who were taking steroid chronically due to any reason, who were unwilling to give informed consent and age over 40 years were out of this study.

III. RESULT

The prevalence of hypertension varies from country to country. It also varies from community to community within the country [1]-[5]. But little is known about Bangladeshi military personnel regarding hypertension, in this study we will highlight frequency of hypertension after 10 years of military services in Bangladesh Army among age group below 40 years of age.

Hypertension was found among 16.3% military service members who met inclusion criteria in this study (Fig. 1). Most of the participants were Sargent, corporal, lance corporal and sainik. 95% participants were married. Majority of the participants’ age group were 30-39 years (Fig. 5). There is a strong association (72.5%) between hypertensive and smoking (Fig. 2). 84% of participants have lack of knowledge regarding hypertension and its complication. 22.5% of hypertensive participants were overweight (Fig. 3). There were very few hypertensive participants were suffering from hyperthyroidism and hypothyroidism 1.2% and 0.8% respectively.

Hypertension runs in family 35% of cases (Fig. 6). Frequency of hypertension found lower who take part in daily exercise > one hour (Fig. 4). Most of the hypertensive individuals were taking their meal from barrack. Already 5% of hypertensive participants developed arterio-venous nipping and 2.5% developed silver wiring (Fig. 8), left ventricular hypertrophy was found among 10% of hypertensive participants (Fig. 9). Raised low density lipoprotein was found among 42.5% and raised triglyceride was found among 60% of hypertensive participants (Fig. 10 and Fig. 11, respectively). Majority of participants were mentally okay (80%) but 16% were frustrated and only 4% were suffering from botheration in their unit activities. Frequency of hypertension increases with increased level of mental stress among the participants (Fig. 7).

Fig. 8. Distribution of hypertensive respondents by changes in fundus (n=40).

Fig. 9. Distribution of hypertensive respondents by left ventricular hypertrophy (n=40).

IV. DISCUSSION

In this study the frequency of hypertension was 16.3% after 10 years of military service in Bangladesh Army. This correlates with other study conducted by Hemma in Pakistan, she found prevalence of hypertension 17.5% among male and 14% among female. [6] Higher prevalence of hypertension was found among male 21.86% and female 19.8% in Wardha, [7] and 23% in Philippines. [8] In 1996 The WHO reported that 20% populations were hypertensive. [9] In United States higher prevalence of hypertension 33.5% found among non-Hispanic blacks and 65.4% among those over 60 years of age. [10] Prevalence of Hypertension 33% was found in Korea, [11] 24% in china [12] and 26% among age 20-35 years in Portugal. [13] Lower prevalence 4.6/1000 population was found among “Oraon” population. [14] These differences are due to different level of blood pressure, study age groups.

To interpret these results some points need to take into consideration that this study was carried out at combined military hospital Dhaka where only 30% of the military personnel (n=245) did not attend the outpatient clinic for data collection. However, we believe that this fact does not affect results interpretation, as the sample was composed of military personnel from all ranks, who developed the different activities. For admission in Bangladesh Army, the individuals are required to qualify some characteristics like certain limit of height and weight, absence of physical or mental disabilities.

Body mass index (BMI) has a strong predictor of hypertension. Raised BMI increase the possibilities of
Hypertension, on the other hand, regular physical exercise protect from hypertension. In this study most of the hypertensive individuals are taking their meal from barak, food source of sainik barak may have some influence on early onset hypertension but needs further study. Hypertensive retinopathy is a chronic process but already 5% of respondents developed early stages of hypertensive changes in fundus. Raised level of LDL and Triglyceride also found among hypertensive respondents. Frequency of hypertension also found more with the increased level of mental stress. So, there are some modifiable risk factors for development of early onset hypertension among military personnel, but further study required regarding this matter.

V. CONCLUSION

Hypertension is one of the leading causes of death in the world. [15] Hypertension affects many organs of the body like brain, heart, kidney, eye etc. Management of Hypertension and its complication not only influence on individual health but also influence on economic development of a country by influencing on national budget and human disability. The effective management of hypertension is therefore a primary health care objective. Hypertension is an emerging health problem in Bangladesh. [16] Despite standards for weight and fitness, military personnel are not immune to hypertension and 16.3% of military service personnel were found hypertensive after 10 years of services.
